

'OUTPUT IMAGE GENERATING OPERATION SERVICE USING NETWORK

BACKGROUND OF THE INVENTION

5 Field of the Invention

[0001] The present invention relates to a technique of providing output image generating operation services over a network.

Description of the Related Art

10 [0002] In commercial printing, image output data that represents a high quality print image is typically generated by carrying out an output image generating operation on its original data. The output image generating operation includes various types of prepress processing such as trapping and RIP to generate high-resolution image output data from low-resolution
15 original data. In this specification, the output image generation operation may be also referred to as "output operation." The output operation using high grade fonts and halftone dots will produce a high quality print which is hardly obtainable from personal printing.

20 [0003] Such operation requires an expensive output operation device, and thus a higher cost. For this reason, a technique for simply and easily carrying out the output image generating operation has been desired in the art. One example of such technique over a network is disclosed in JP 2003 ·
76509A.

25 [0004] In the output image generating operation over a network, most clients prefer to carry out operations on trial basis and check for qualities or results of the operations prior to their actual use of the result to create printed materials. However, access to the output image generating operation service is generally restricted for commercial reasons and is difficult to be open to the public seeking trial use. Even if trial use is possible, there is still a problem
30 that the operations for authorized clients may be delayed due to increase in requests for trial use.

SUMMARY OF THE INVENTION

[0005] In one aspect of the present invention, there is provided a method of executing an output image generating operation job requested from a client device in an output operation execution system that is connected with the client device via a network. The method includes the steps of: (a) providing within the output operation execution system a paid operation queue for registering orders of paid operation jobs and a trial operation queue for registering orders of charge-free trial operation jobs; (b) receiving from the client device a request for execution of either a paid operation job or a trial operation job; (c) entering the requested operation job into either the paid operation queue or the trial operation queue; (d) selecting an operation job to be executed while giving priority to the paid operation jobs in the paid operation queue over the trial operation jobs in the trial operation queue; (e) generating image output data by executing the selected operation job, and storing the image output data into a storage device of the output operation execution system; (f) if the executed operation job is a paid operation job, the output operation execution system transferring the image output data to the client device without undesired modification; and (g) if the executed operation job is a trial operation job, the output operation execution system adds to the image output data a trial-job mark indicating that the image output data has been made by trial operation, and transferring the image output data to the client device.

[0006] According to this method, a user of the client device can execute an output image generating operation simply and easily by requesting a charge-free trial operation job. Since the paid operation jobs are selected and executed in preference to the trial operation jobs, an inconvenience that the paid operation jobs are excessively delayed due to the trial operation jobs can be prevented.

[0007] The present invention may be embodied in various forms, such as a method of executing output operation jobs and a method of managing output

operation jobs, a system for output operation execution and a system for output operation job management, a network system including such execution and management systems and client devices, a computer program for implementing functions of such system for output operation execution or of 5 such client devices, a recording medium storing such computer program.

[0008] These and other objects, features, aspects, and advantages of the present invention will become more apparent from the following detailed description of the preferred embodiments with the accompanying drawings.

10 BRIEF DESCRIPTION OF THE DRAWINGS

[0009] Fig. 1 is a block diagram illustrating a network system according to one embodiment of the present invention.

[0010] Fig. 2 is a block diagram illustrating a structure of a job management system 120.

15 [0011] Fig. 3 is a flowchart showing process procedures in the present embodiment.

[0012] Figs. 4(A) and 4(B) schematically show an image that is obtained from a paid operation job and an image that is obtained from a trial operation job.

20 [0013] Fig. 5 is a flowchart showing the contract procedure.

[0014] Fig. 6 illustrates a screen of output history list.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0015] Fig. 1 is a block diagram illustrating a network system according to 25 one embodiment of the present invention. This network system includes an output operation execution system 100 and a client device 200 that are connected via a network NET such as Internet. The output operation execution system 100 includes a Web server 110, a job management system 120, and output operation devices 131 through 133. The system may be 30 provided with at least one output operation device. The job management system 120 is connected with a storage device 140 that is composed of a hard

disk device. The storage device 140 stores data regarding a user of an output operation service, operation queues that will be described later, and image output data.

[0016] The client device 200 uses a browser to display a variety of Web
5 pages that are transferred from the Web server 110. Input results by the user
on the Web pages are transferred to the output operation execution system 100
via the network NET. A typical personal computer can be used as the client
device 200.

[0017] The client device 200 is connected with an image recording device
10 210. The user of the client device 200 can use the image recording device 210
to record images in visible forms based on image output data that are
transferred from the output operation execution system 100. A variety of
15 output devices can be used as the image recording device 210, including a plate
output machine that makes press plates, a film output machine that makes
halftone films, a proof sheet printer that outputs proof sheets, a color printing
machine that outputs printed materials directly.

[0018] Fig. 2 is a block diagram illustrating a structure of the job
management system 120. The job management system 120 includes an
operation queue entry module 122, an operation job selecting module 124, an
20 output data transfer module 126, and a user entry module 128. The
operation queue entry module 122 enters an operation job requested by the
client device 200 in either a paid operation queue Q1 or a trial operation queue
Q2. The operation job selecting module 124 makes reference to these
25 operation queues Q1, Q2 and selects an operation job that is to be executed by
the output operation devices 131 through 133. The output data transfer
module 126 stores image output data that have been generated in the output
operation devices 131 through 133 into the storage device 140 (Fig. 1), and also
transfers the image output data to the client device 200. It should be noted
30 that the output data transfer module 126 can directly connect to the network
NET without via the Web server 110 to transfer the image output data to the
client device 200. The user entry module 128 enters information regarding

trial users (users that request execution of trial operation jobs) or contract users (users that can request execution of paid operation jobs).

[0019] Fig. 3 is a flowchart showing the procedure of the present embodiment. The operation queue entry module 122 receives an operation request (a request for execution of an operation job) from the client device 200 in step S1. A contract user can request a paid operation job; whereas a trial user (or a non-contract user) can only request a charge-free trial operation job.

[0020] The request for operation job, for example, includes the following information:

- 10 (1) a title of the operation job and/or a job ID;
- (2) original data representing images or characters of original;
- (3) various settings of output image generating operation process (parameters for each prepress process such as a trapping process and a RIP process and a format of image output data); and
- 15 (4) user information.

[0021] The operation queue entry module 122 determines whether the operation job is trial or paid in step S2, and enters the job into the corresponding operation queue Q1 or Q2 in step S3 or S11. The operation job selecting module 124 selects a job to be executed out of the two operation queues Q1, Q2 in steps S5, S12, and S13. The paid operation queue Q1 only has paid operation jobs, which are arranged in an order of descending priorities; whereas the trial based operation queue Q2 only has charge-free trial operation jobs, which are also arranged in an order of descending priorities. In the present embodiment, the order of priority in each operation queue is set according to the order of entry. Furthermore, the order of priority of the paid operation jobs is always set higher than that of the trial operation jobs. Accordingly, a paid operation job in the paid operation queue Q1 is selected in step S4, S5, even if a trial operation job that was entered much earlier still remains in the charge-free operation queue Q2. On the other hand, if the paid operation queue Q1 has no remaining jobs and the trial operation queue Q2 has one or more jobs, the trial operation jobs are selected

in the order of descending priorities in step S12, S13. Since the paid operation jobs are selected in preference to the trial operation jobs in the present embodiment as described above, there is advantageously no possibility that execution of the paid operation job that has been requested by the
5 contract user may be delayed due to the trial jobs. The operation job selecting module 124 causes one of the output operation devices 131 through 133 to execute the operation job thus selected. The output operation process at least includes RIP (Raster Image Processing), which is a process of generating image output data that is used to output a print image in a visible form, such
10 as a printed material and a printing plate.

[0022] Once informed of termination of the operation from the output operation device, the output data transfer module 126 temporally stores the image output data thus generated into the storage device 140 in step S7. As for a paid operation job, the image output data is transmitted in step S9 to the
15 client device 200 as it is, that is, without undesired modification to the image output data. As for a trial operation job, the image output data is added with a trial-job mark and is transmitted to the client device 200 in step S14, S9. Fig. 4(A) illustrates an example of an image that is represented by the image output data, which is the result of the paid operation job; whereas Fig. 4(B)
20 illustrates the same image that is added with the trial-job mark. This trial-job mark represents characters "FOR EVALUATION" overwritten on the almost entire image. The trial user is provided with the image output data that is attached with such trial-job marks. Since the output image for trial use has the same quality as the image that can be obtained from the paid
25 operation job, except for the trial-job marks, the user can check the quality of the service that is provided by the output operation execution system 100.

[0023] The non-contract user is allowed to make a contract on paid services via the network. Fig. 5 is a flowchart showing the contract procedure. Once the user accesses the Web server 110 from the client device 200 and applies for
30 the paid operation contract, the user entry module 128 executes a process that is required for making the contract in step S21. Once the contract is made,

.the user is allowed to submit a request for image output data that are stored in the storage device 140 in step S22. Fig. 6 is a screen of output history list that is displayed on the client device 200 according to the information transferred from the Web server 110. The display screen includes IDs of 5 operation jobs that were executed in the past, titles of the operation jobs, dates and times of completion of the jobs, formats of image output data, sizes of the image output data, and contract type. In this example, the contract type is in "trial" for every job.

[0024] The user can download trial image output data or paid image output 10 data by checking a leftmost check box CHB and by pushing a get trial data button B1 or a get actual data button B2. It should be noted, however, that only the contract user can download actual data without undesired modification or the paid image output data.

[0025] As described above, the storage device 140 temporarily stores image 15 output data without trial-job marks also for trial use before the contract is made on paid operations. Additionally, as shown in Fig. 6, each image output data is set to have a term of validity and is attached with an indication showing whether or not the data is within the term of validity. The indication of valid term information can take other forms such as an indication 20 of a last day of the term of validity. When the user requests for transfer of data that is within the term of validity, the output data transfer module 126 reads the corresponding image output data from the storage device 140 and transfer the data to the client device 200 in step S23, S24. Data that is out of the term of validity is deleted from the storage module 140. When the user 25 requests for transfer of data that is out of the term of validity, the client device 200 displays on its screen an indication that shows the data is not valid in step 25.

[0026] In this way, in the present embodiment, the user can execute charge-free trial operation jobs and check for their image qualities even before 30 the contract is made on paid operations. After making the contract on paid operations, the user can execute paid operation jobs, and obtain image output

data that were generated for trial operations, which allows for an effective use of operation results. The user can also obtain output operation results in shorter time. Since the paid operation jobs are executed in preference to the trial operation jobs in the embodiment described above, execution of the paid 5 operation jobs is not delayed due to the trial operation jobs.

[0027] C. Modifications:

[0028] C1. Modification 1:

A variety of marks other than the characters "FOR EVALUATION" may also be used for the trial-job mark that is to be attached to the image 10 obtained from the trial operation job. The trial-job mark is preferably provided onto the entire image in a uniform way.

[0029] C2. Modification 2:

In the embodiment described above, the paid operation jobs are set to have priority over the trial operation jobs all the time as long as any paid 15 paid operation job remains in the paid operation queue Q1. Alternatively, the paid operation jobs may be set to have higher priority when a priority is assigned to a job or when the priorities are updated. Specifically, the trial operation jobs may be assigned with lower initial priorities than the paid operation jobs when the priority is assigned, and the paid operation jobs may 20 have their priorities upgrading faster than those of the trial operation jobs when the priority of each job is upgraded as time goes on. Such a case also fulfills the condition that "the paid operation jobs registered in the paid operation queue have higher priorities over the trial operation jobs in the trial operation queue."

25 [0030] C3. Modification 3:

The trial operation jobs may also be imposed with restrictions that are severer than those imposed on the paid operation jobs in respect of data capacity and operation execution time. This will further reduce the possibility that execution of the paid operation jobs may be delayed due to the 30 execution of the trial operation jobs.

[0031] C4. Modification 4:

The contract on paid operation service may take various forms such as a contract with limited term, a continuous contract with unlimited term, an individual contract on particular operation jobs, and the like.

[0032] Although the present invention has been described and illustrated 5 in detail, it is clearly understood that the same is by way of illustration and example only and is not to be taken by way of limitation, the spirit and scope of the present invention being limited only by the terms of the appended claims.
